Effective data sharing definitions

- 'Effective data sharing' –relies upon 'high quality structured data' being fully shared, without limitations, for open interrogation and for aggregation with complementary data sets.
- 'Effective data' or 'High quality structured data' –
 Implementation of a rigorous data standards
 environment following approaches such as FAIR
 (Findable, Accessible, Interoperable and Reuseable)
 and The Dublin Core Interoperability levels.
- Semantic Interoperability when high quality data is inter-connected on the internet in a meaningful way to create new knowledge and medical breakthroughs

Recent history and the data sharing landscape

- Enshrined in European Public Policy 'open access to document' Vienna agreement
- Cochrane Institute and Ben Goldacre consistent voices
- Reaction is EMA policy 0070 'Study reports' 'summary data and results' next steps will be Patient Level Data
- Pharma response Datasphere.com
 ClinicalStudyDataRequest.com, academic Yoda, AllTrials,
 Vivali
- European Commission making research data open by default
- WHO, Wellcome, Médecins Sans Frontières etc statement

with good structured data we are creating knowledge aggregating knowledge into wisdom is the aim wisdom that leads to medical breakthroughs our goal

Motivations/Why?

- Connect the worlds healthcare data (costs per year of maintain and achieve of \$300-700 million per year for semantic interoperability but potential savings in healthcare of \$30 billion per year in the USA alone
- McKinsey have made other estimates for cost savings for open data in healthcare of up to \$300 billion.
- Why to find cures, more precise medicines, improved public Health, save lives, create efficiencies

Data sharing/Collaboration

+extensive coordination:

academic, professional-

governments, industry,

communities

'Optimised Public Health' i.e. WHO SDG-3 Level 4 (Maximised potential from medical research & Billions \$£¥€ saved in research) +Fully standardized and Full Learning Healthcare System linked:Systems, FAIR'ification of Data standards, ontologies Full Semantic Interoperability and translations +linked domain Linked: open data, domain models, systems models BRIDG,OMOP data lakes - more reliable disease models, integrated data sources + linked Ontologies +broader data sharing · graph databases - easier & stronger data inferences and confidence, Level 3 + RDF & Merged collaborative Full lifecycle dataflow to inform Personalised + broad data integration efforts i.e. datasphere Medicine: RWD, Big, Omics, EHR, Clinical with CDSR and Opentrials Collaboration: Metadata registries, repositories +transport standards +wider collaboration: (RESTFUL, ODM2,CTR2, (OpenTrials, CDSR, Datasphere, IMI etox, eTRIKS) high quality data sharing, Level 2 FHIR, Research efficiencies, shared biomarkers precompetitive focus, + SHARE API biomarkers & public Broader data aggregation +Domain Models (BRIDG) disclosure Rich and live data registries, MDRs Structured data: + data collection and analysis + limited success in data standards (CDISC SEND, SDTM, · GCP & regulatory conformance sharing with CROs + Level 1 safety/efficacy improvements ADAM, metadata: Trace, define) **Partners** Clearer signal detection +basic controlled vocab Data reuse/efficiency +therapeutic area standards Poor data reuse & aggregation Level 0 -minimum -minimum Degraded data inferences Low % of reproducibility

Standards implementation

5 top problems

- 1. Data standards are not consistently mandated/recommended by govt/funders/foundations
- 2. Standards are not applied consistently, implementation curves too steep, current low MDR use,
- 3. Data isn't shared fully: fenestrated data or licencing or anonymization issues
- 4. More resources: Creating and maintaining semantic interoperability and standards is complex the sector needs more hands, more funding, more government support.500,000 data stewards.
- 5. More co-ordination less innovation and less duplication of terminologies and Domain Models.

Level 1

 + data collection and analysis standards (CDISC SEND,SDTM, ADAM,metadata: Trace,define)
 +basic controlled vocab
 +therapeutic area standards

Structured data:

- · GCP & regulatory conformance
- safety/efficacy improvements
 - Clearer signal detection
 - · Data reuse/efficiency

+ limited success in data sharing with CROs + Partners

- 1. Creating data atoms quality high enough to be Interoperable and Re-useable/reproducible, the essential I & R of the FAIR data principles.
- 2. For data sharing essential to used established anonymization techniques i.e. Phuse Feran, Emman et al 2015
- 3. It is the clinical research findings that are shared which are the foundation to stratifying medicines for precision medicine
- 4. Controlled vocabularies and shared ontologies, Biomedical concepts, CDISC RDF and RDFS and SKOS for the semantic Web.

Use Case: Improve registries via structured and connected data: Clinical research & Patient/Disease

Avoiding Vioxx incident - Had the data for Vioxx and other similar cox2 inhibitor drugs such as Naproxen been made available many of the estimated 40,000 deaths might have been avoided and Merck would have avoided the 4.85 billion dollar joint law suit.

- Reporting of clinical trials is now mandatory in USA and Europe but that reporting must be timely – late submissions ignored for over 1billion in fines
- Standards exist for ingredients of drugs to be recorded in a structured format –
 FDA working on IPD dictionary so medicines using like ingredients can be cross analysed
- Results for Preclinical studies are not mandated by law in Europe whereas
 SEND is mandated in USA. pre-clinical data is an essential ethical right Anderson & Kimmelman 2012
 - Early detection of ADRs i.e. BIA 10-2474 preclinical studies showed deaths in primates at high dosage, same in first in man studies – 1 death and several serious ADRs.

 C. Glenn Begley et al identified 53 preclinical 'landmark' oncology papers in top journals. Only 47 of 53 could be replicated

- 'The loss of empirical studies are sinkholes in the medical landscape'
- Grave danger in clinical interventions being made on poor data assumptions
- With the future being AI and deeplearning data must be solid

Collaboration: Metadata registries, repositories

(OpenTrials, CDSR, Datasphere, IMI etox, eTRIKS)

- Research efficiencies, shared biomarkers
 - Broader data aggregation
 - Rich and live data registries, MDRs

+wider collaboration: high quality data sharing, precompetitive focus, biomarkers & public disclosure

Collaboration has already facilitated:

- Broad consensus on Domain Models: BRIDG,
 OMOP, CIMI, IDMP
- Implement Meta data registries for share consistent standards implementation SHARE
- Data Sharing efforts OpenTrials, CDSR, Datasphere
- Precompetitive efforts such as IMI showing success

Collaboration: Metadata registries, repositories

(OpenTrials, CDSR, Datasphere, IMI etox, eTRIKS)

- Research efficiencies, shared biomarkers
 - Broader data aggregation
 - Rich and live data registries, MDRs

+wider collaboration: high quality data sharing, precompetitive focus, biomarkers & public disclosure

Deeper collaboration needed...

- Complete beginning to end standards: extending protocol, trial registration and results summaries
- Convergence of standards to enrich the data i.e. CDISC with IDMP, ODM2.0/FHIR –
- Further sharing of pre-competitive data for de-duplication of effort i.e. Drug repurposing
- Elimination of placebo arms?

CTR2 Case Study - https://www.cdisc.org/ctr2-project

- Registry information is key to informing decision making:better registries means better business analytics for pharma and future A.I initiatives,
- better pharmacovigilance,
- De-duplication of effort i.e. more effective drug repurposing
- A CTR2 standard would better inform future EDC templates
- Efficiency and cost savings in disclosure of trials

Potential Clinical Trial Registry Improvements

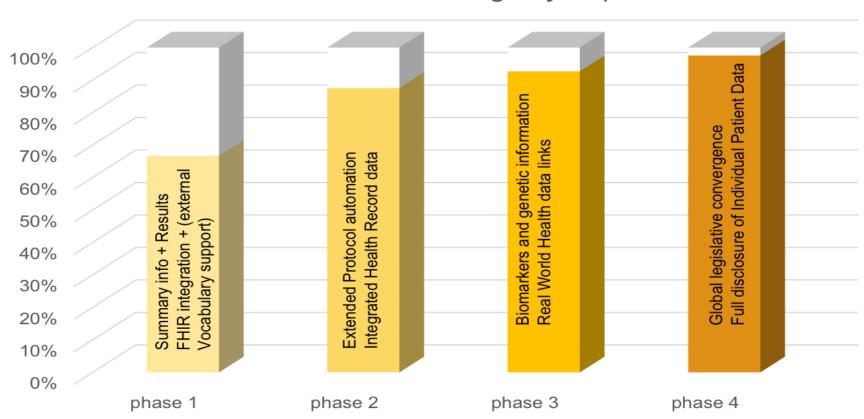

Figure 3. Moving registries towards fully structured registries with broad integrated data sources inkeeping with the 'hierarchy of data returns' paradigm

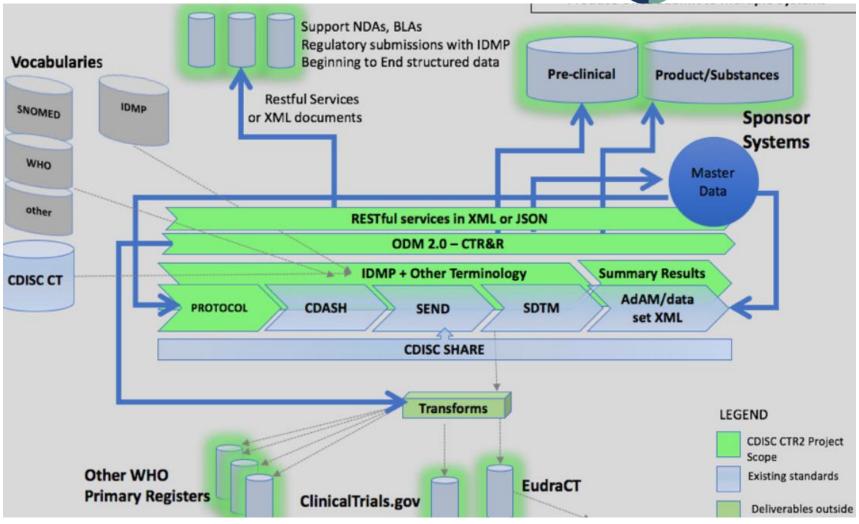

Figure 3.1 Moving registries towards fully structured registries with broad integrated data sources inkeeping with the 'hierarchy of data returns' paradigm

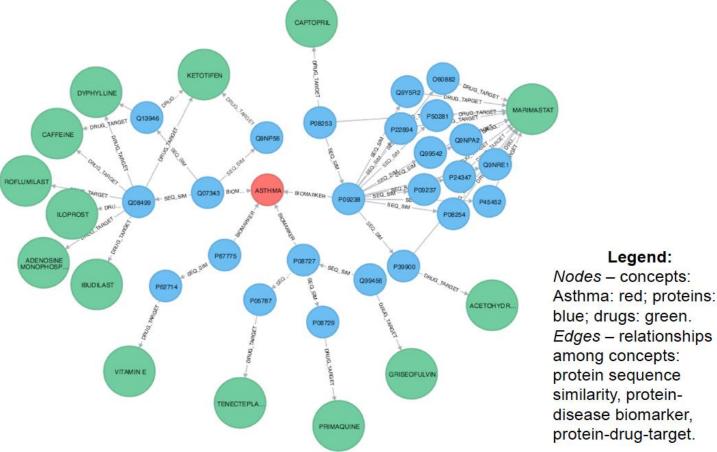

+linked domain models BRIDG,OMOP + linked Ontologies + RDF + broad data integration

Linked: open data, domain models, systems

- data lakes more reliable disease models, integrated data sources
- graph databases easier & stronger data inferences and confidence,
 - Full lifecycle dataflow to inform Personalised Medicine:RWD,Big,Omics,EHR,Clinical

+broader data sharing & Merged collaborative efforts i.e. datasphere with CDSR and Opentrials

Cypher: MATCH (drug:Drug)<-[r1:DRUG_TARGET]-(p1:Protein)-[r2:SEQ_SIM]- (p2:Protein)-[r3:BIOMARKER]-({DiseaseName:"ASTHMA"}) RETURN r1, r2, r3 limit 30

"life sciences involves modeling of an incomplete and ever-changing model of how our bodies work and what we know about it."

by September 2011 there were 31 billion RDF statements, 504 million RDF links

Today, we even have <u>medical doctors playing with Cypher queries</u>, demonstrating another important implication of this project: a shift in mindset towards truly interdisciplinary effort of clinicians and data scientists.

RDF potential

- Once expressed in RDF, information can be represented, accessed, computed, integrated, and exchanged without the need for any translations
- provides a universal, mathematically precise, and computable language that can express a wide range of information – ideal for integrating wide data sources
- platform independence and semantic interoperability are inherent

The CDISC Mission and Principles:

- Recognize the ultimate goal of creating regulatory submissions that allow for <u>flexibility in scientific content</u> and are <u>easily interpreted</u>, understood, and navigated by regulatory reviewers.
- Acknowledge that the data content, structure, and quality of the standard data models are of paramount importance, independent of implementation strategy and platform.
- Work with other professional groups to encourage that there is <u>maximum sharing of information</u> and <u>minimum</u> <u>duplication of efforts.</u>

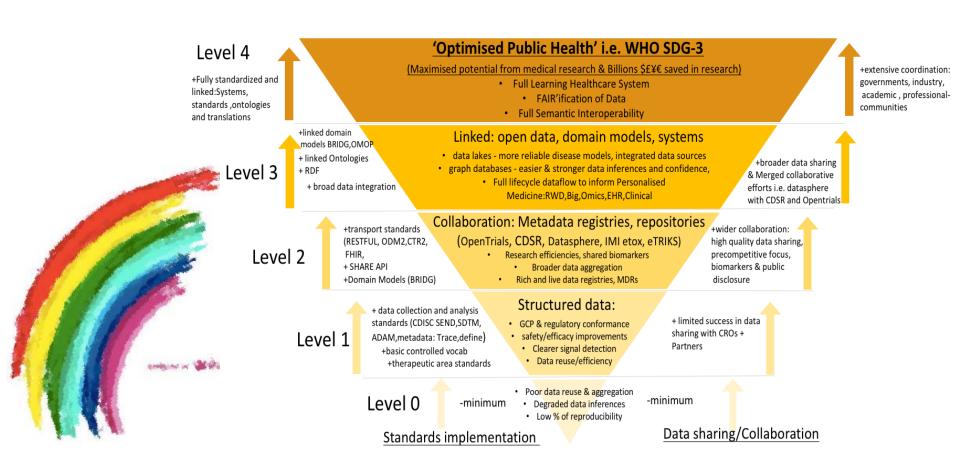

Top 5 Recommendations (from the 25

recommendations of the publication)

- Improve registries via structured and connected data:clinical research & Patient/Disease
- Merge siloed data sharing efforts through collaborative models.
- Wider publication and sharing of data concepts and semantic relationships particularly between ontologies; a formal LOD diagram
- Increase investment in precompetitive data and knowledge sharing (too many RDF data sets not updated regularly)
- 5. Validating the representations of the terminology using constraints
 - expressed in RDF Data Shapes using SHACL extend CDISC RDF

Level 4 is an achievable pot of gold at the end of the rainbow

But we all need to be on board with selling the data sharing agenda
